

# Terrestrial Remote Sensing @ Department of Remote Sensing

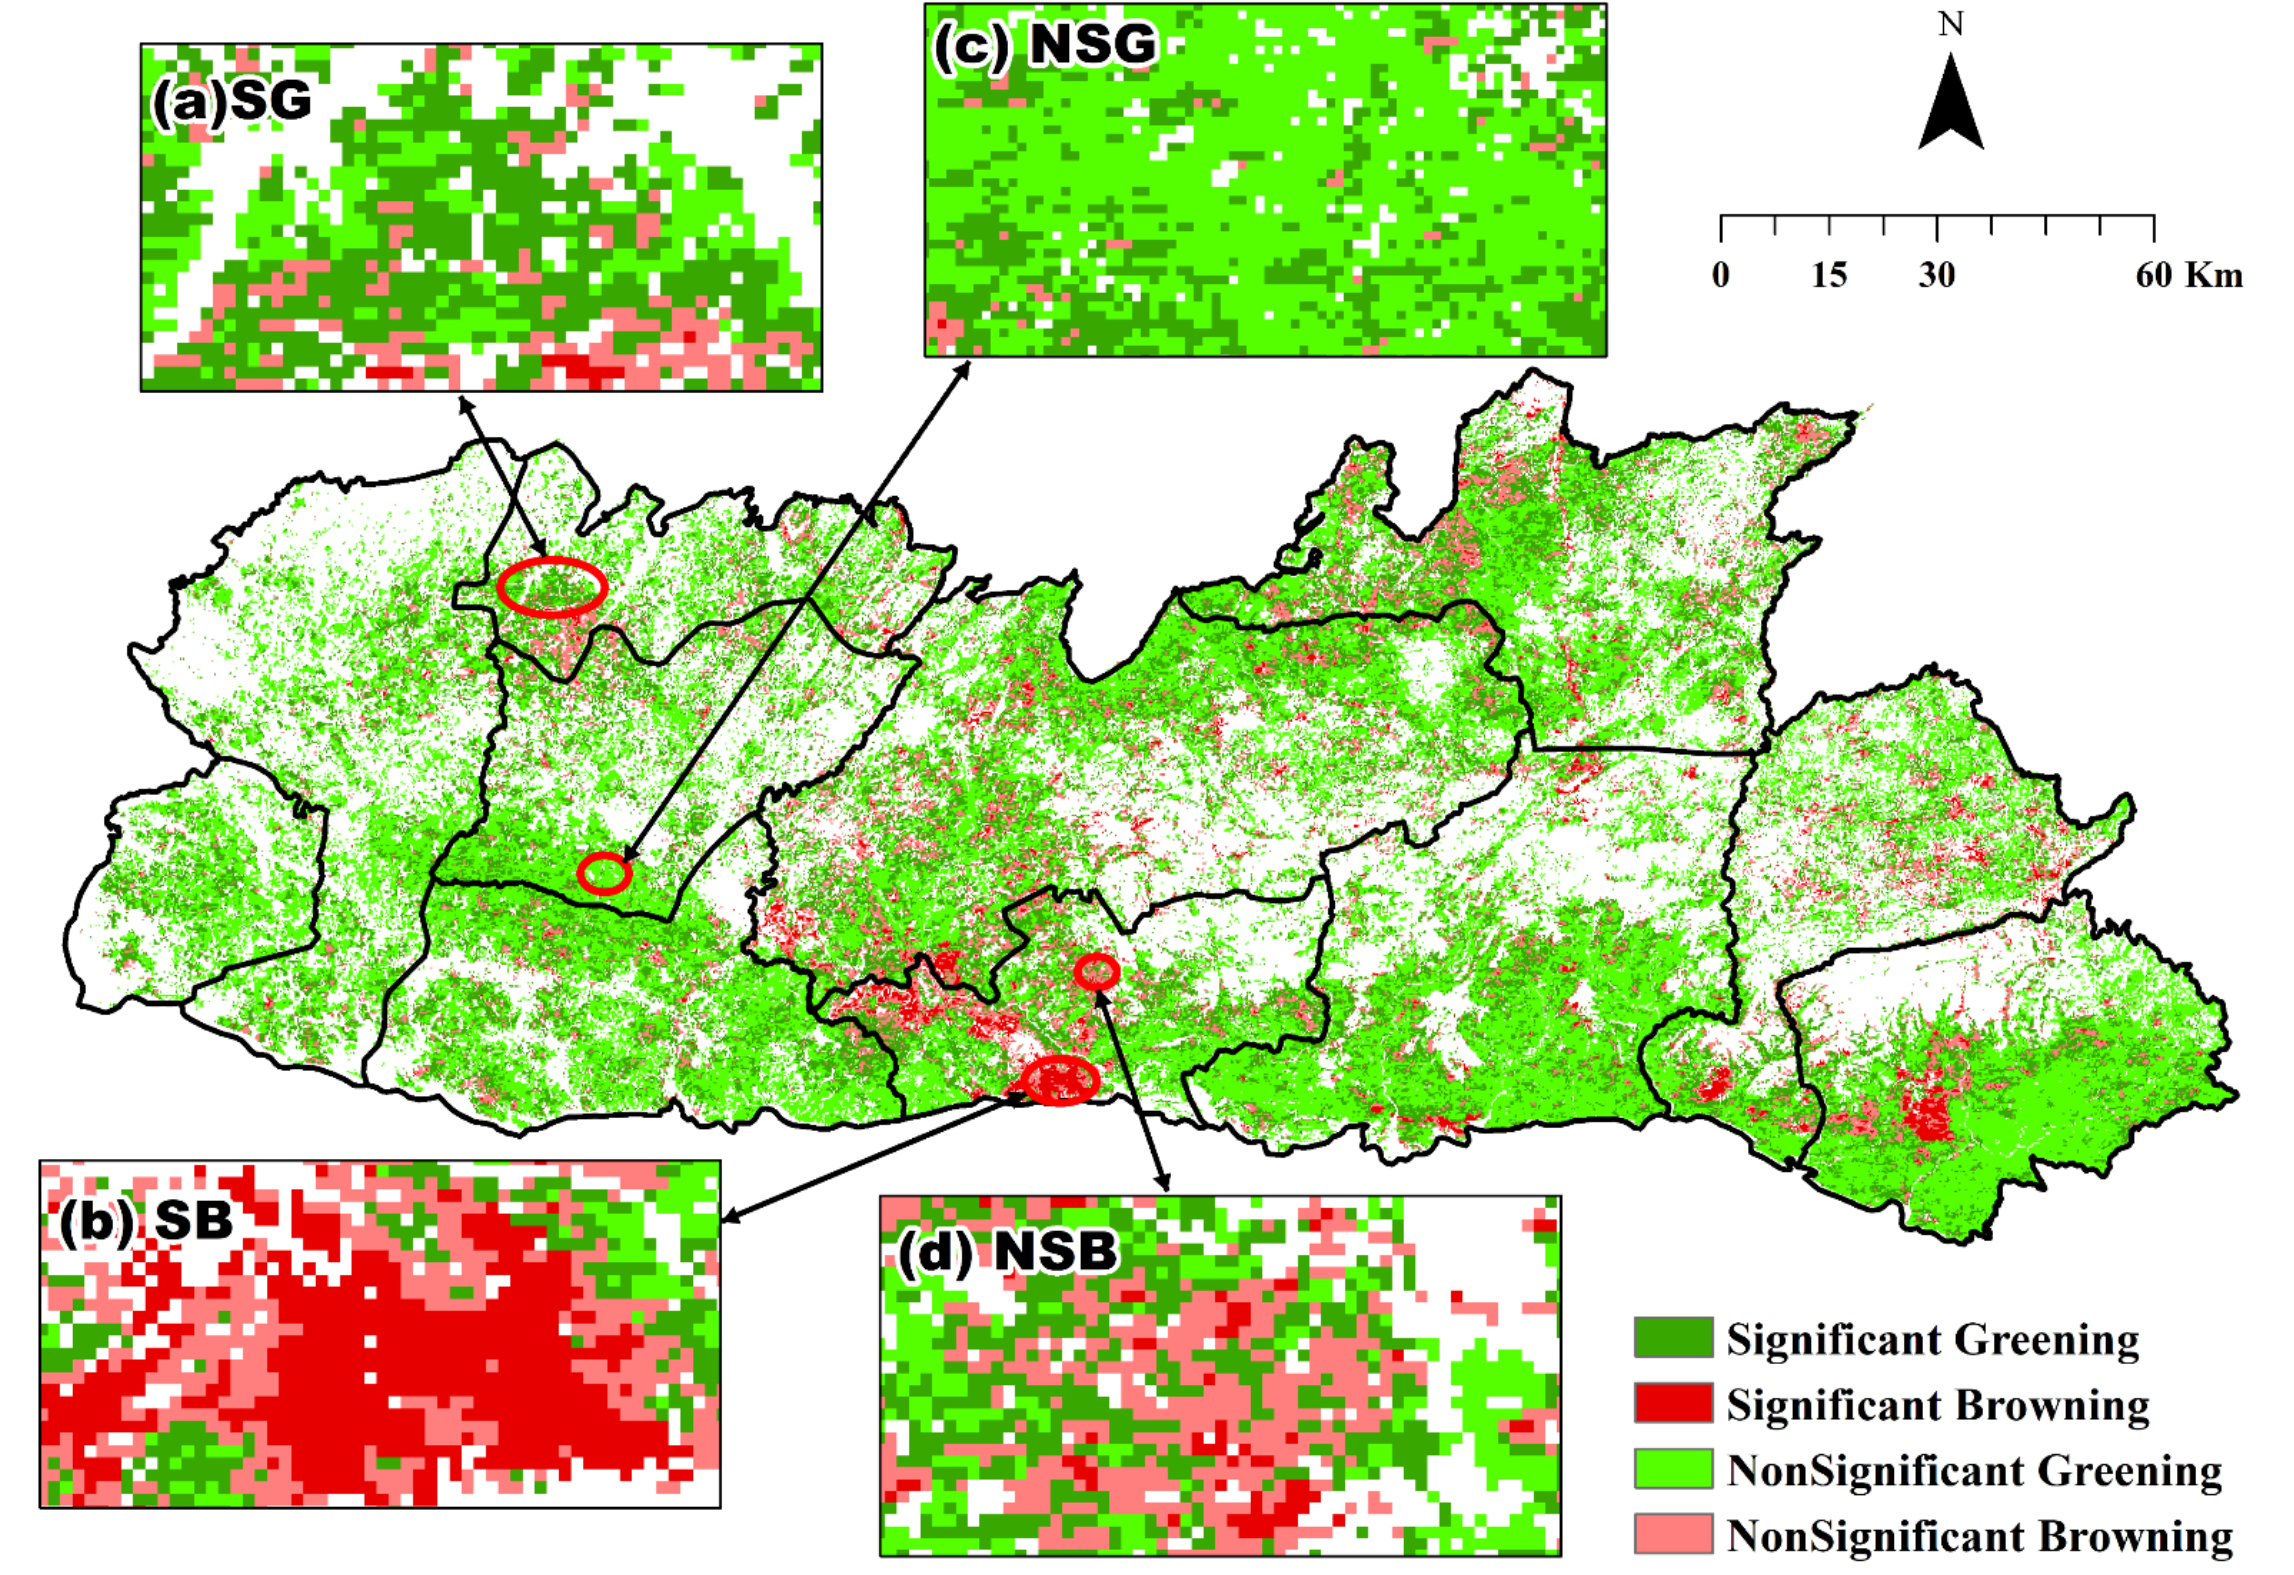

## TERRESTRIAL REMOTE SENSING

### Major Research Areas

- Modelling Space-Time vegetation dynamics
- Land Surface Phenology
- Climate Change Impact Analysis
- Soil Moisture Studies
- Soil Erosion Risk Analysis
- Landscape Metrics and Modelling
- Morphometric analysis and Watershed management
- Landslide Susceptibility Assessment and Zonation

## Monitoring and Modelling Vegetation Dynamics and Climatic Controls

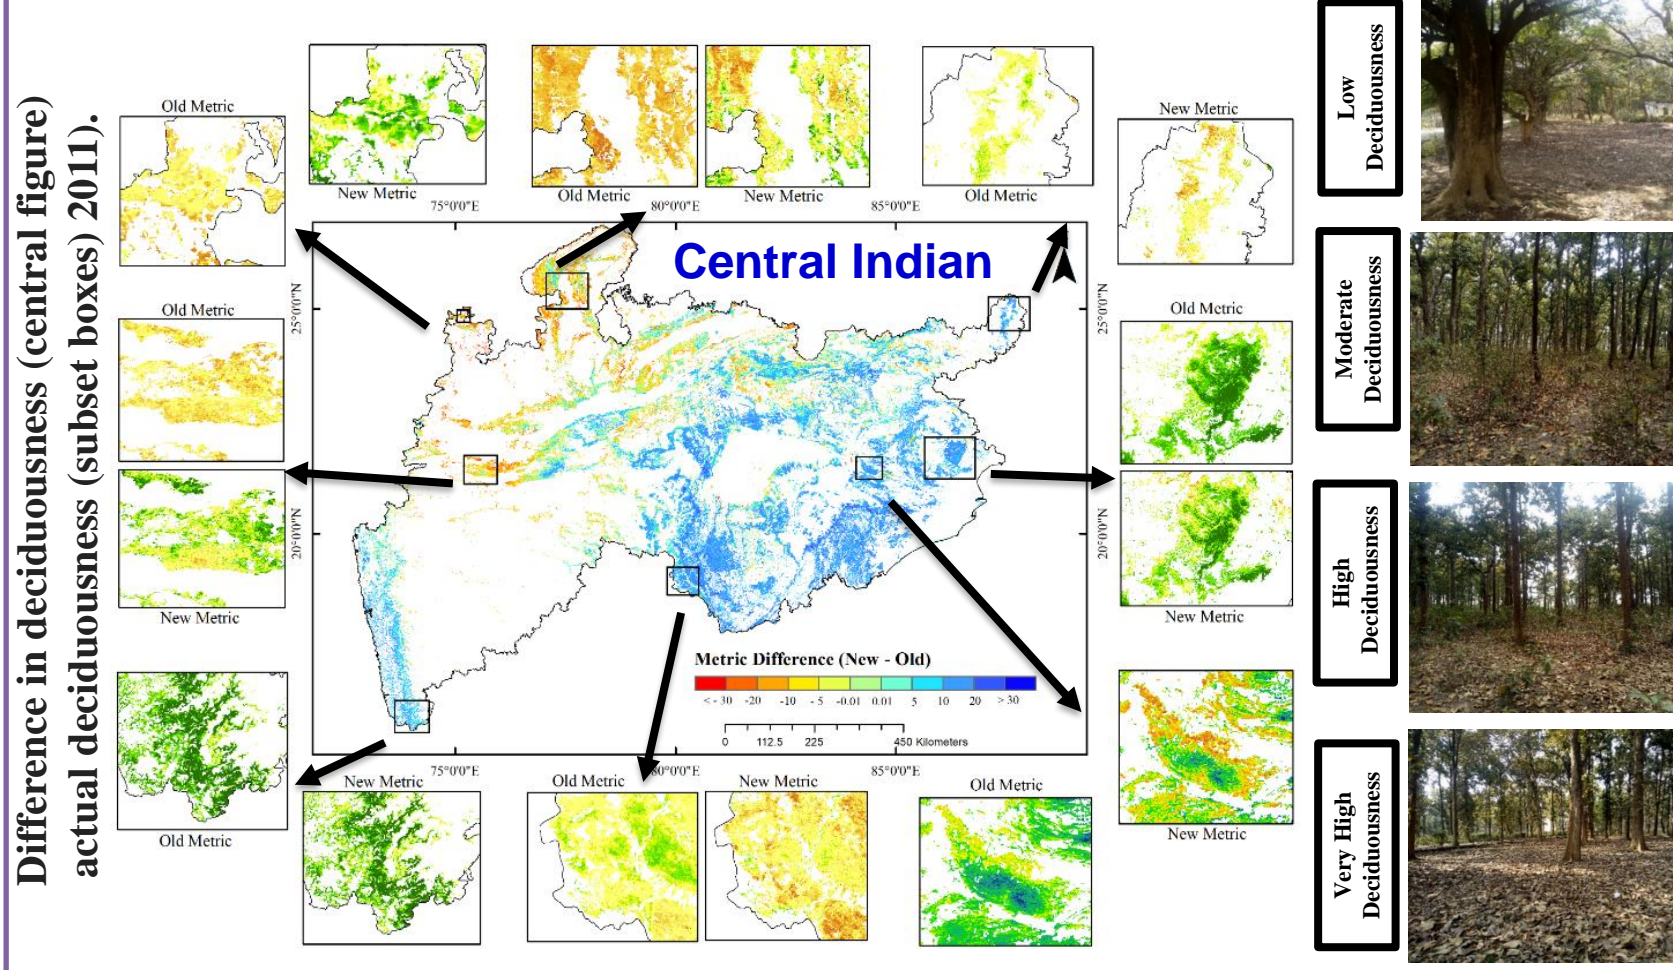

### Major findings

- 'Greening' indicates positive climate-vegetation feedback.
- Temperature Controls the vegetation growth in Meghalaya

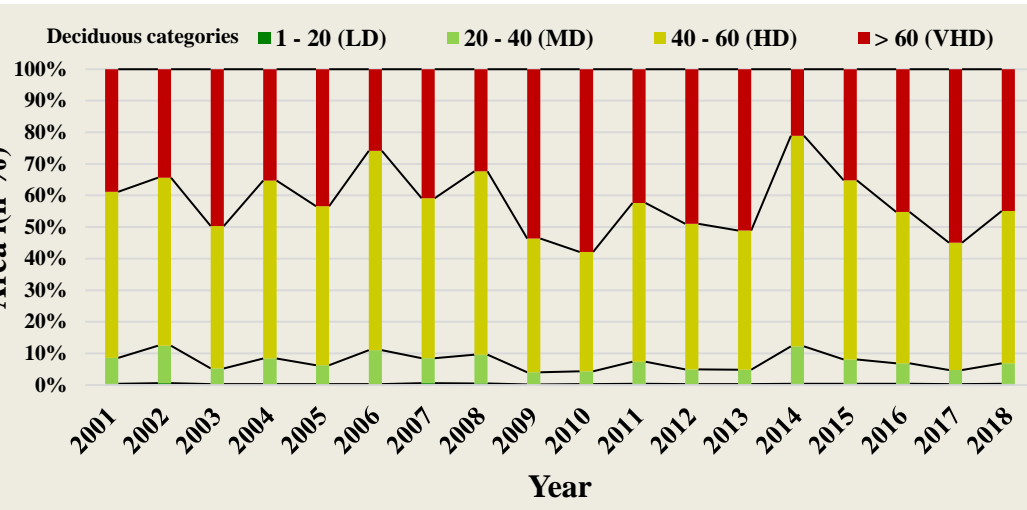

Bhuyan et al., 2022(Under Review)

## Leaf-Fall Estimation from Satellite Data

**Objective:** Develop metric and quantifying leaf-fall using remotely derived Satellite data.

### Performance of Old and New Improved Metric

Temporal variation in the percentage area of different categories of deciduousness

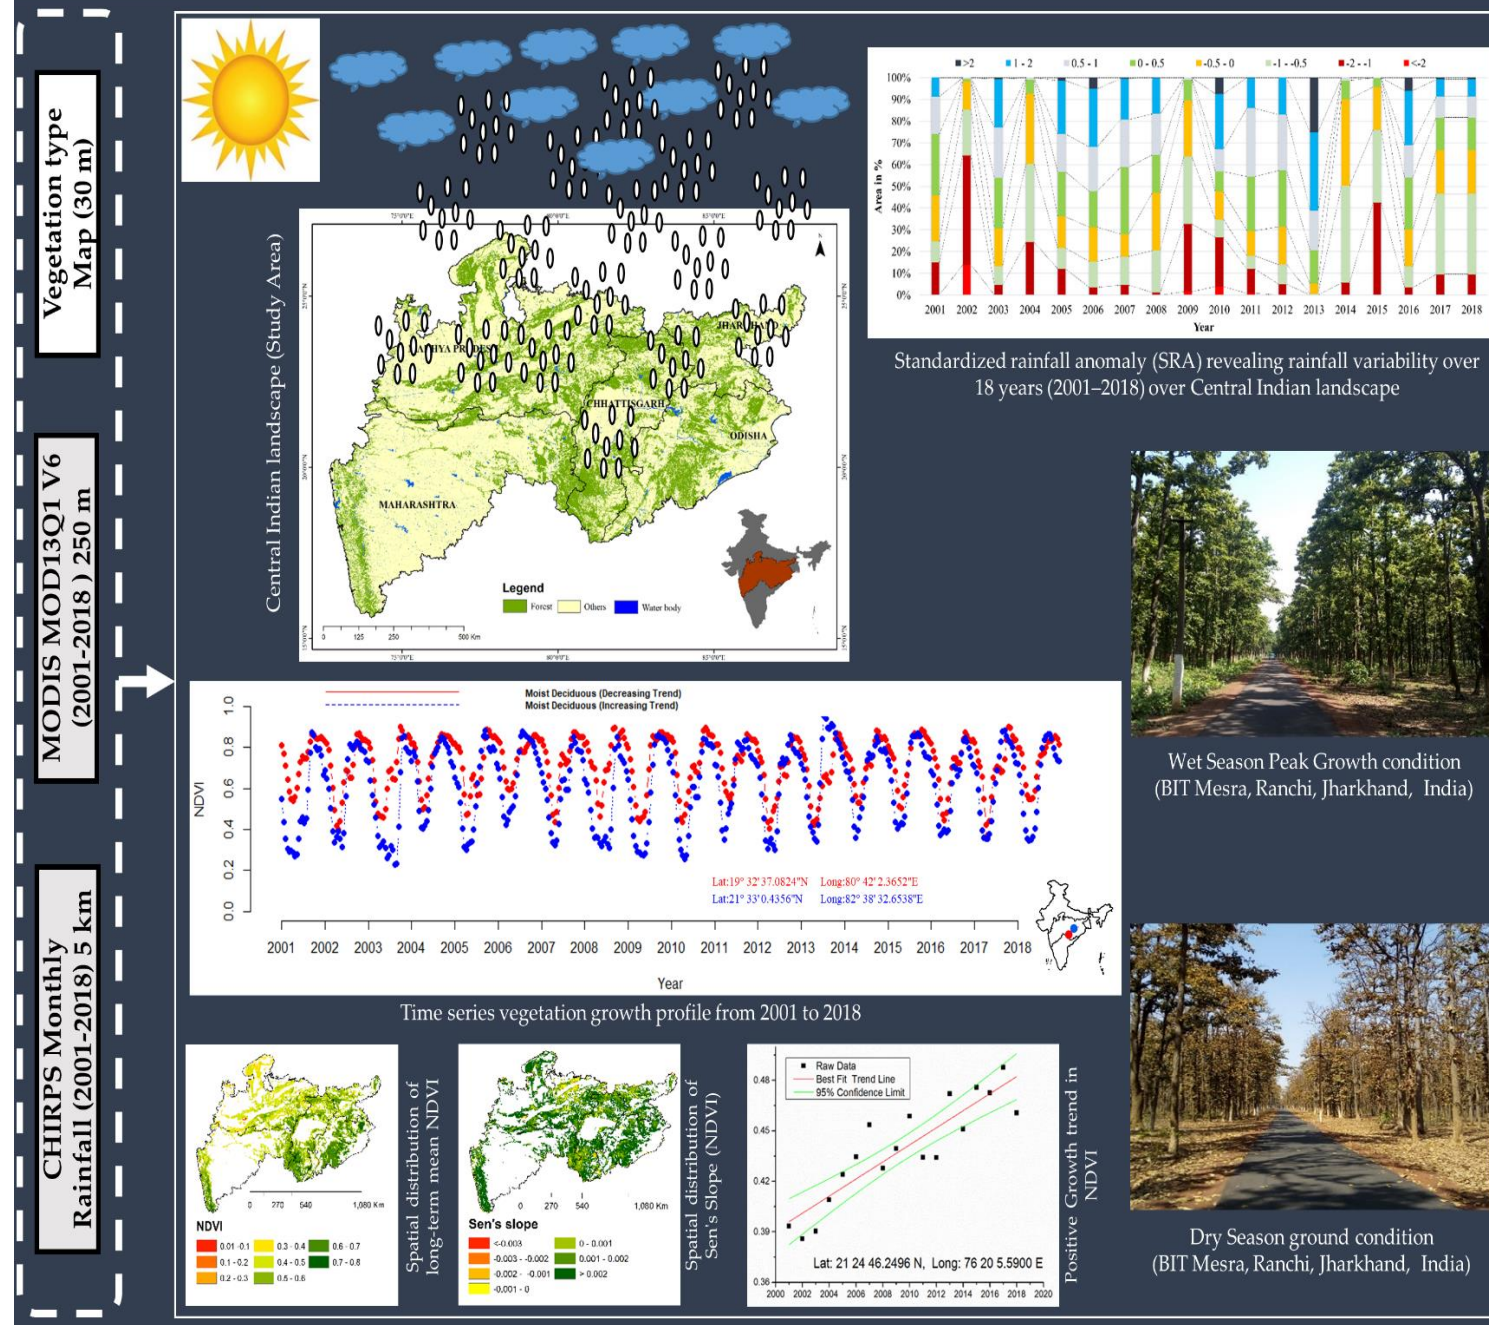

### Major findings

- Quantity of leaf-fall was less in water scarce years
- Our metric showed clear relation to ground observation in different forest types and
- Differentiate the deciduous and non-deciduous characteristics of tropical forest.

Singh et al., (2020)

## Resilience of Central Indian Vegetation to rainfall variability

**Question:** Is the central Indian landscape resilient to rainfall variability?

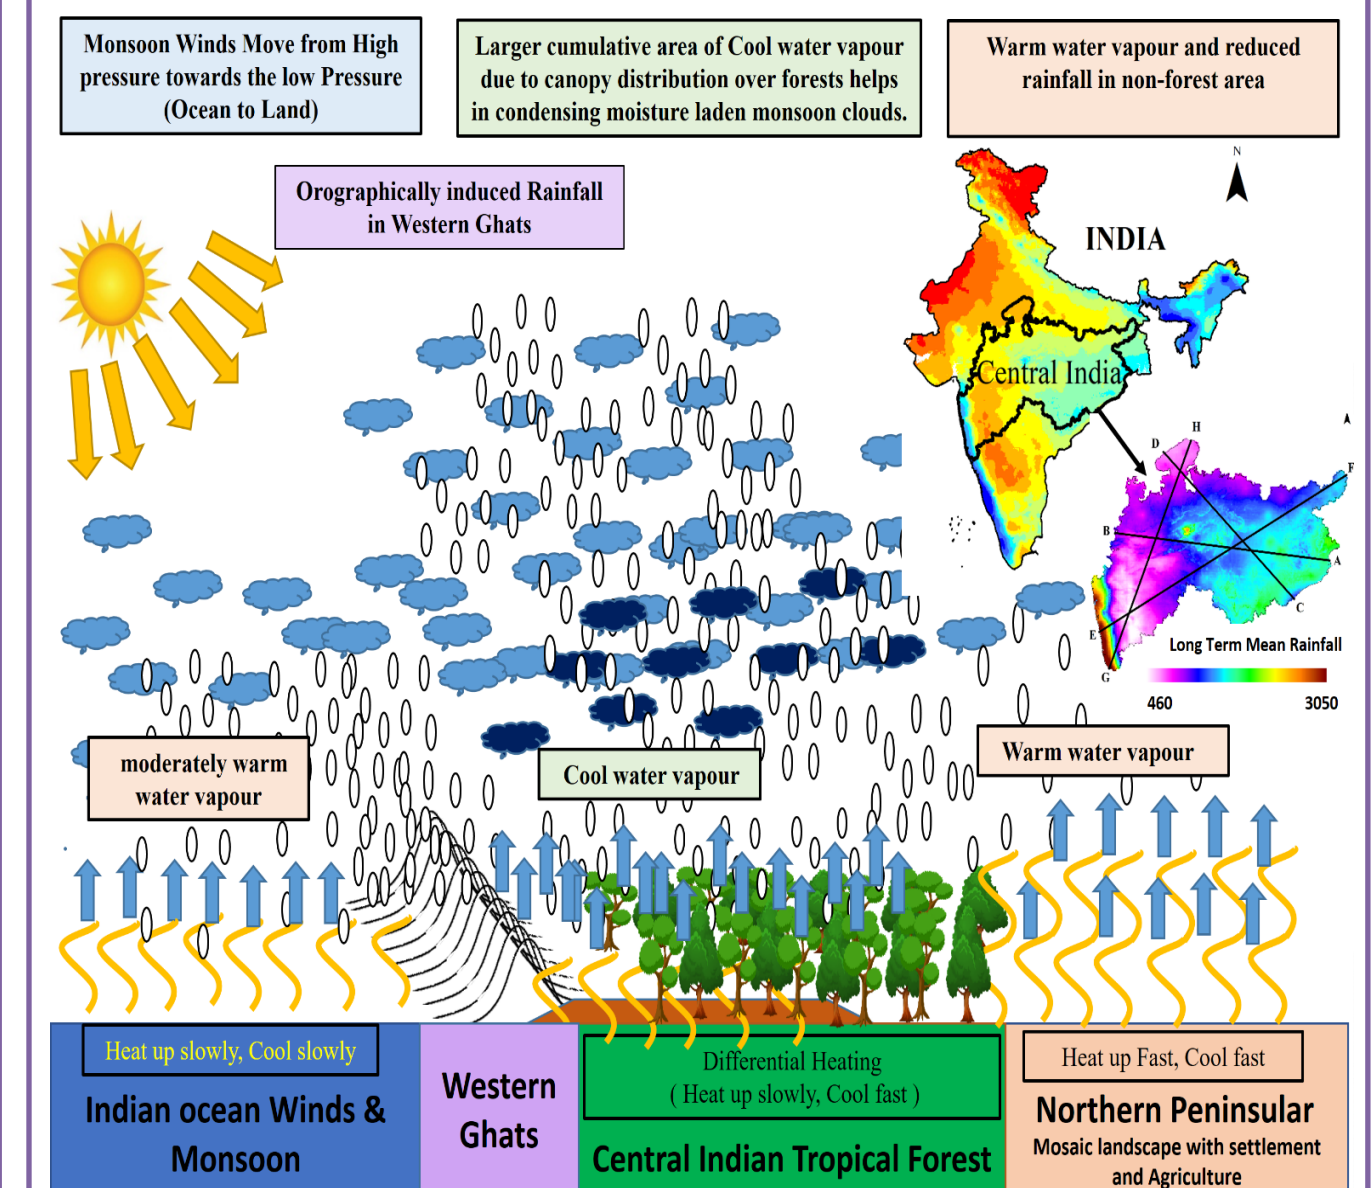

### Major findings

- Rainfall is the key climate variable in Central India
- Resistance to dry spells and water scarcity was Observed
- High resilience to rainfall variability and High water use efficiency relative to climatic oscillations.

Singh et al., (2021)

## Influence of Central Indian forests on Rainfall

**Question:** Do central Indian Forest have influence on regional rainfall pattern?

### Major findings

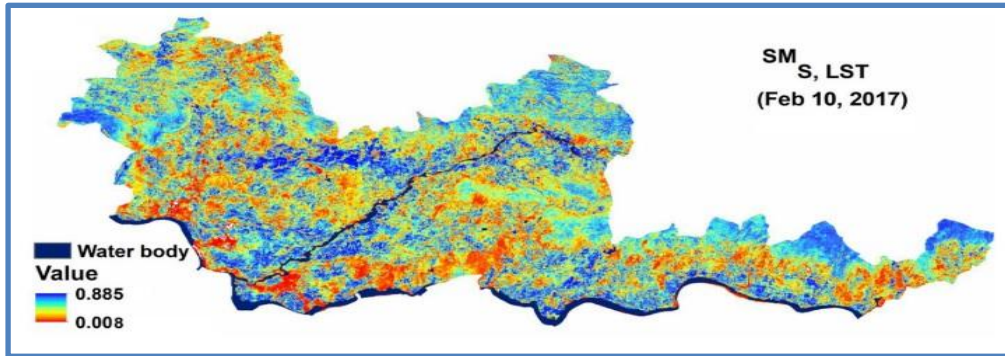

- Reduction in rainfall as we move away from the forest patches.
- Dependence of rainfall on forests which act as condensation machine for central Indian landscape

Singh et al., 2022 (Submitted)

## Estimation of surface soil moisture

**Objective:** To derived soil moisture from High resolution Satellite data.

### SPATIAL VARIATION

### TEMPORAL VARIATION

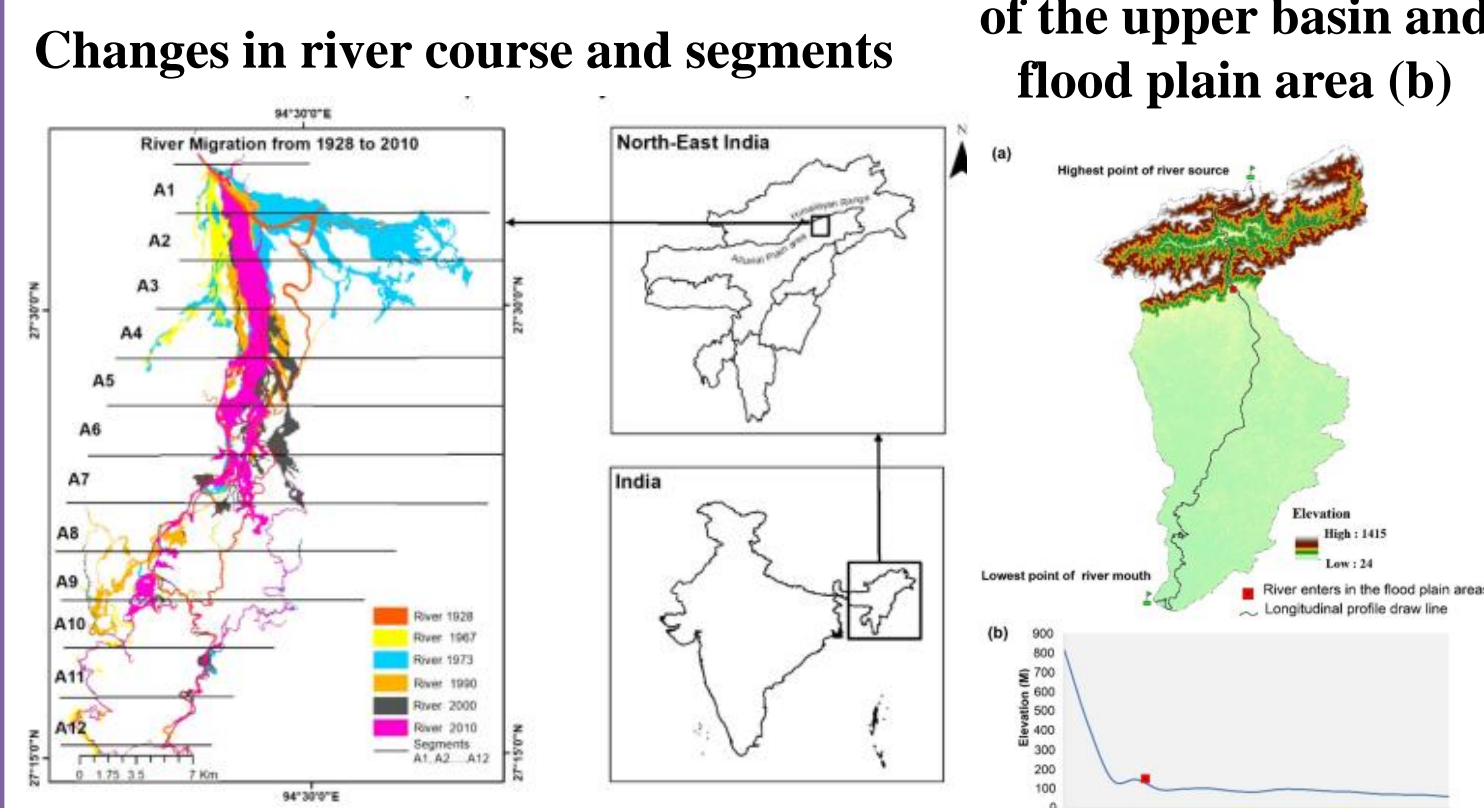

### Major findings

- Volumetric surface soil moisture was estimated (0-5 cm)
- End-members would vary with spatial and temporal variation.
- Standardization method gives higher temporal accuracy.

Koley & Jeganathan (2020)

## Remote Sensing based estimations of river channels migration

**Question:** Do Jadhral river changes it course during 1928 to 2010?

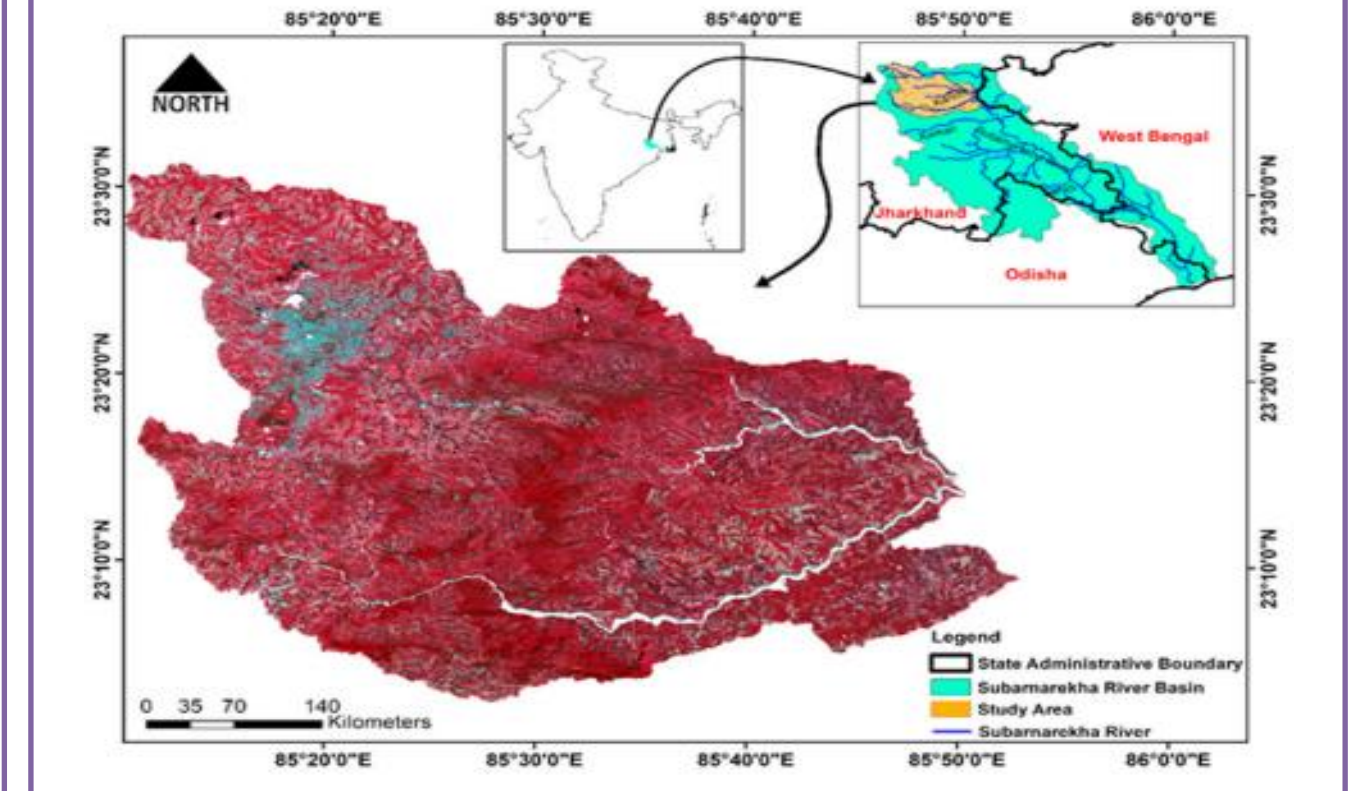

### Major findings

- River bank line frequently migrated upto 20.56 km in segment A5 during 1967–1973. River thalweg migrated 45.6 and 52.6 m/year in segments A11 and A12 from 1928 to 2018.
- Significant LULC changes occurred during 1967–1973 and 1990–2000.

Saur & Rathore (2022)

## Geomorphic Control On Soil Erosion

**Question:** Do Universal Soil Loss Equation (USLE) have potential to determine different geomorphological landforms?

### Major findings

- Correlation analysis revealed the occurrence of highest and negative correlation of the erosion estimate with PC5.
- Topography factor is found to be pre-dominant among al factors.
- Structural Hill exhibits significantly different erosion estimate with the maximum landform units.

Kathwas & Patel (2021)
